

# Acoustic Technology Used in Hunt for Flight Recorder at Helicopter Crash Site

A mission to search for the wreckage of an Irish Coast Guard helicopter which crashed into the Atlantic earlier this year, killing all four crew members, was supported with underwater locating equipment from Sonardyne International Ltd. Within hours of rescuers arriving at the scene of the accident off the west coast of Ireland, Sonardyne Scout USBL and ROV-Homer acoustic tracking and relocation systems, owned and operated by the country's Marine Institute, had detected emergency signals being transmitted from the aircraft's flight data recorder (FDR).

Using an ROV, search teams were subsequently able to pinpoint the exact location of the wreck which was lying in 40 metres of water.

Rescue 116, a Sikorsky S92 search and rescue helicopter operated by Canadian Helicopter corporation (CHC) on behalf of the Irish Coast Guard, disappeared from radar screens at 12.46am on 14 March 2017 in the vicinity of Blackrock, an isolated rocky islet.

As part of the emergency response, Ireland's Air Accident Investigation Unit (AAIU), together with the Irish Coast Guard, requested equipment and personnel from the Marine Institute to assist with the initial search for the wreckage. This included the Scout USBL system which was mobilised on a local fishing vessel and onsite within four hours of the institute's team arriving.

## Flexible Mobilisation

The system is typically used for tracking divers, ROVs and underwater vehicles in waters up to 1,000 metres and is designed to be operated from virtually any type of vessel, small or large. [Scout](#) is portable, quick to setup and easy to use making it ideal for short underwater surveys and operations.

Following a three hour search, the Scout picked up the first faint signals from the aircraft's 37.5kHz Dukane underwater locator beacon attached to its flight data recorder - or 'black box.' This was despite rough sea conditions and the vessel often operating within 50 metres of the rocky coastline.

The Marine Institute deployed its Work-class ROV and using the data from the Scout search, operators were able to navigate the ROV to the wreck site. The ROV was also equipped with a Sonardyne ROV-Homer system which was used to 'home' directly in on the signals from the Dukane pinger. To make moving around through the debris field easier for the ROV's pilot, a number of transponders compatible with the ROV-Homer were deployed to act as navigation waypoints. Irish navy divers later recovered the flight recorder which was found to be in good condition and transferred it to the UK for analysis.
